Logging is a set of best practices used to help identify and understand important aspects of application behavior and identify potential points of attack. Logging is a broad term that can encompass any type of log output. It can be structured, semi-structured, or unstructured. The type of log you use will depend on the type of application you are developing and where you are in the lifecycle of the application. DataStudio can be configured to collect data for logging in a few different ways. These include: Adding new source data in the DataStudio GUI and exporting it to a file Adding a log in a library for your data connections Adding logging directly in your application DataStudio Logging In DataStudio, there is a Logging tab on the Data

Sources tab of the Manager. Click on this tab and you will see the list of available logging options. You can choose to enable any of the logging options or not. Enable the option, and add one or more selected options to the table. Importing When you import a table from the application source, the data is automatically formatted as a proper DataSet and stored in the DataWindow (see Figure 1). If the table has any errors, or the table fails to import, you will be prompted with the following dialog. Figure 1: Import dialog If you choose to cancel the import, the data in the window will be reset to the original format and any errors will be fixed. If you choose to overwrite the table, the table will be re-written to a DataSet. You will be prompted for the following dialog. Figure 2: Overwrite dialog The table will be rewritten to a DataSet, and any errors will be fixed. As of version 1.6, a new option was added to allow you to use the same table multiple times in a single DataWindow. The next step in the lifecycle is when the application is put into production. At this point, you can create a final log of all of the errors and mis-behaviours that occurred in the application. This helps to diagnose any problems, and determine the most efficient way to implement a fix. To create a logging window, click on the Logging tab, and then click the Create New Log Window button. This will open the Create Log Window dialog. You can create a new log window for any of your existing data connections. 82157476af
